INTRODUCTION

Charleston Harbor, South Carolina, is the site of an important commercial port and a U.S. Navy Base. Water depths throughout the entire area are typically shallow, and maintenance dredging is necessary to keep access channels at their prescribed depth because of shoaling. Ships enter the harbor via an entrance channel protected along its inner reaches by a pair of rubble jetties. The Charleston Harbor Project, authorized by the River and Harbor Act, provides that the entrance channel be maintained at a depth of 35 feet and a width of 1000 feet from the sea to the inner end of the jetties (U.S. Army Engineer District, Charleston, 1975). The depth of the entrance channel is maintained using a hopper dredge, and dredged material is disposed in an open ocean disposal area just south of the jetties. According to the Corps report, volumes ranging from 367,460 to 1,410,000 cubic yards of dredged materials have been disposed over this site annually since FY 1965.

Relatively little is known about the marine life and sedimentologic processes of the Charleston Harbor Ocean Disposal Area and vicinity. The South Carolina Wildlife and Marine Resources Department (1972) conducted trawl surveys of the area and found relatively few species and low numbers of individuals compared with inshore estuarine areas. However, no thorough benthic sampling has ever been conducted in the area and no data base exists which might be used to assess the impact of disposing dredged material there. A reconnaissance survey of bottom sediments at the mouth of Charleston Harbor was conducted by the U.S. Coast and Geodetic Survey for the U.S. Navy in 1951. This was largely a gear test experiment and yielded very few quantitative grain size analyses.

During September 1978 the Charleston District, U.S. Army Corps of Engineers

entered into a contract with the South Carolina Wildlife and Marine Resources Department for benthic and sedimentologic studies of the Charleston Harbor Ocean Disposal Area and vicinity. The goals of this study were to:

(1) Characterize the species composition and density of benthic communities in areas subjected either to deposition of dredged material or to resulting sedimentation;

(2) Assess the effects of dredged material disposal on bottom communities in the disposal area;

(3) Describe the mineralogic and textural characteristics of the bottom sediments in and about the Charleston Harbor Ocean Disposal area and the bottom sediments of the Charleston Harbor Entrance Channel.

(4) Describe the sediment bedforms present in and about the Charleston Harbor Ocean Disposal area as to size, orientation, and composition (mineralogy and texture).

(5) Ascertain whether the sediment characteristics of the study area have been altered by current disposal practices.

(6) Provide a data base for appraising the effects of deposition of dredged material from Charleston Harbor in the Ocean Dispoal Area.

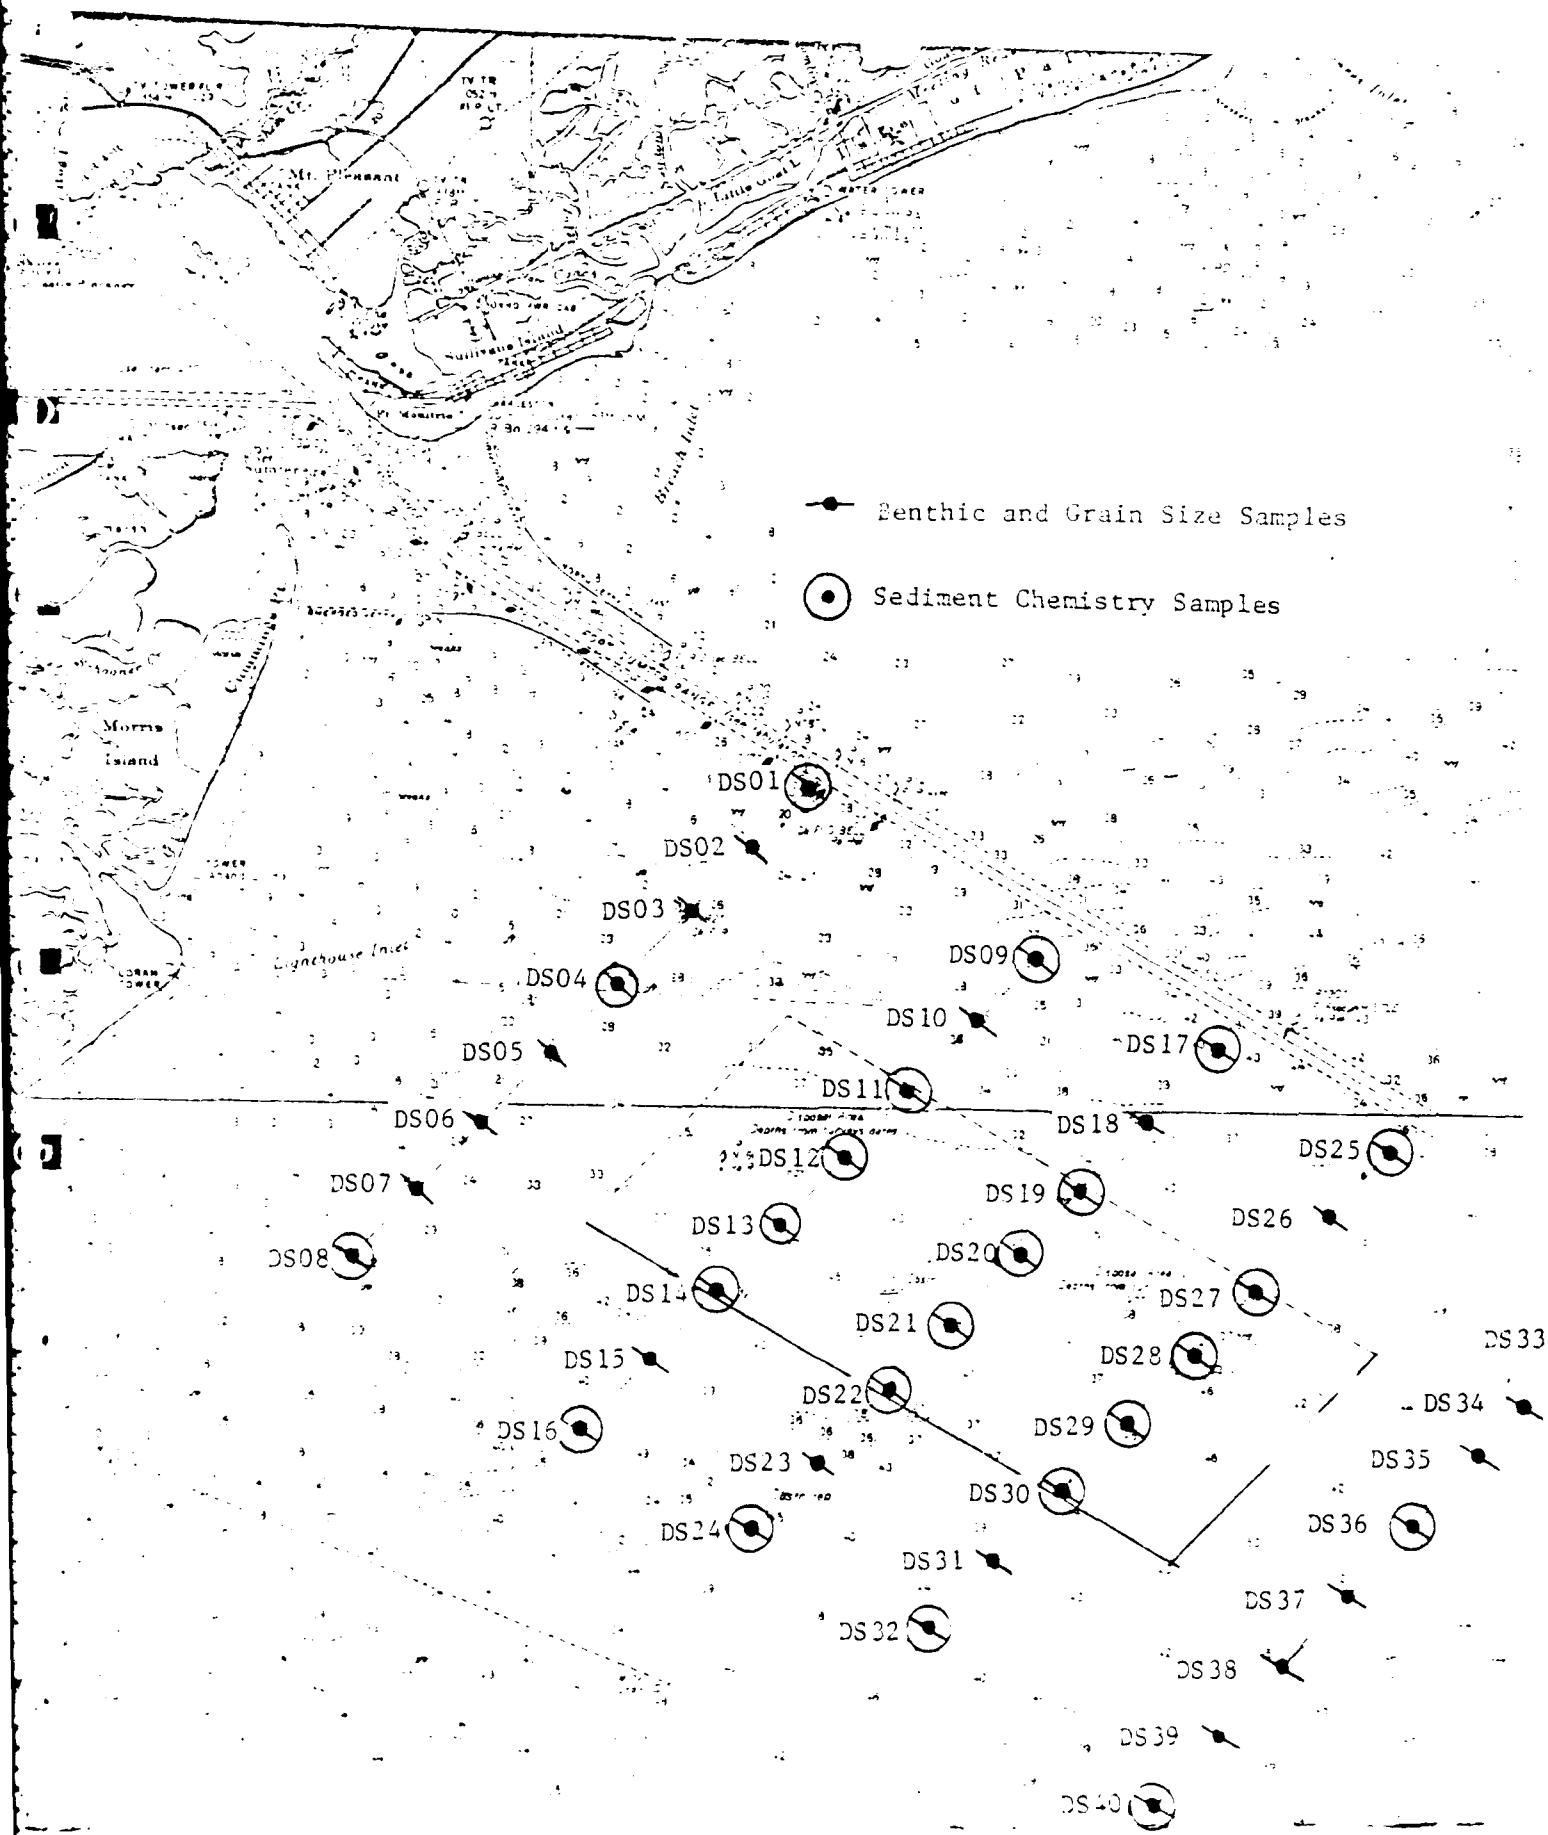
MATERIALS AND METHODS

Benthic Ecology

Sampling of the benthos was undertaken at 40 stations in and adjacent to the Charleston Harbor Ocean Disposal Area during August 1978. Stations were arranged in five transects, with each transect having eight stations (Fig.1). Three of the transects crossed the Ocean Disposal Area, while the other two extended outside the disposal site to the north-west and south-east, respectively. This array of stations provided a total of 12 sampling sites within the Ocean Disposal Area and 28 sites outside. Stations were located using Loran-C aboard the R/V ATLANTIC SUN, and the research vessel was anchored at each site for all sampling except dredge tows.

Quantitative benthic samples were collected using a 0.10 m^2 Smith-McIntyre grab. Five replicate samples were taken at each of the 40 stations. After measuring the volume of the grab samples, collected materials were washed through a 1 mm sieve. Organisms and sediment remaining on the sieve after washing were removed to appropriately labelled gallon jugs or bottles, stained with rose bengal, and preserved in 10% seawater formaldehyde. Collections were returned to the laboratory for sorting, identification, and enumeration of the fauna.

Quantitative samples were supplemented with qualitative samples of the epifauna taken using a 30 kg modified oyster dredge. The dredge consisted of a rectangular steel frame measuring 80 cm across the mouth, with a 1.5 m long bag of 2.5 cm stretch mesh polypropylene. A skirt of interlacing metal rings protected the bag from chafing. A single tow of five minutes was made at each station. After preliminary sorting of the catch in the field, unidentified epifaunal invertebrates and representative sample of firm substrates were



...ocation of the Charleston Harbor Ocean ...
...disposal area and the sampling stations.

preserved in 10% seawater formalin and returned to the laboratory for examination and identification.

After identification and enumeration of the fauna from quantitative samples, benthic community structure was analyzed using the following equations (Pielou, 1977):

(1) Species diversity (Shannon's formula)--

$$H' = -\Sigma pi \log_2 pi$$

where H' is the diversity in bits of information per individual, and $pi = \frac{ni}{N}$ or the proportion of the sample belonging to the i^{th} species.

(2) Species richness--

$$SR = \frac{S-1}{\ln N}$$

where S is the number of species and lnN is the natural logarithm of the total number of individuals of all species in the sample.

(3) Evenness or equitability--

$$J' = \frac{H'}{\log_2 S}$$

where H' is the species diversity in bits of information per individual and S is the number of species.

Water Chemistry

Surface and bottom water chemistry samples were collected at each station using a Van Dorn bottle. Parameters measured included temperature, salinity, dissolved oxygen, nitrates, silicates, phosphates, turbidity, and suspended and settleable solids. Water temperatures were measured in the field from stem thermometers mounted inside the Van Dorn bottles. All other samples were returned to the laboratory for analysis. Salinity samples were analyzed using a

Beckman Model 65TB Induction Salinometer. Dissolved oxygen was determined by the modified Winkler titration method (Strickland and Parsons, 1972). Nutrients were analyzed using a Technicon Auto Analyzer II. Turbidities were measured using a Hach Model 2100A turbidimeter. Solids were determined using standard Methods 224C and 224F (American Public Health Association, 1971).

Sediment Chemistry

Separate samples were taken with the Smith-McIntyre grab at 24 stations to obtain sediments for geochemical analysis (Fig. 1). Collected sediments were placed in one-gallon plastic bags, immediately frozen in dry ice, and delivered to the contracting officer at the Charleston District, U. S. Army Corps of Engineers for shipment to the Corps' South Atlantic Division Laboratory, Marietta, Georgia. At this laboratory, analyses were made to determine volatile solids, total organic carbon, BOD, Kjeldahl nitrogen, ammonia nitrogen as NH_3, nitrite nitrogen as NO_2, nitrate nitrogen as NO_3, oil and grease, lead, zinc, mercury, soluble phosphorus as PO_4, total phosphorus as PO_4, iron, cadmium, arsenic, chromium, nickel, copper, beryllium, selenium, and vanadium.

Sedimentologic Investigations

Bottom sediments were sampled using a Smith-McIntyre grab in the Charleston Entrance Channel and the Charleston Harbor Ocean Disposal Area. Bottom bedforms were directly observed, measured, and sampled by divers in the Ocean Disposal Area (Fig. 2).

Sediment samples were analyzed for quartz sand, calcium carbonate shell, silt, and clay content (weight percent). Silts and clays were separated from sand-size material by wet sieving or washing through a 62 μ screen. Silt was separated from clay by pipette analysis. Calcium carbonate shell was separated from the quartz sand-size material by HCl digestion. Quartz sand-size fractions were sieved for 20 minutes in a nest of ½ Ø Tyler screens; resultant grain

size distributions were described by statistical moment measures calculated by the GRAPE computer program. These grain size distributions were decomposed into their bi-normal components using the R-KE computer program (Clark, 1976).

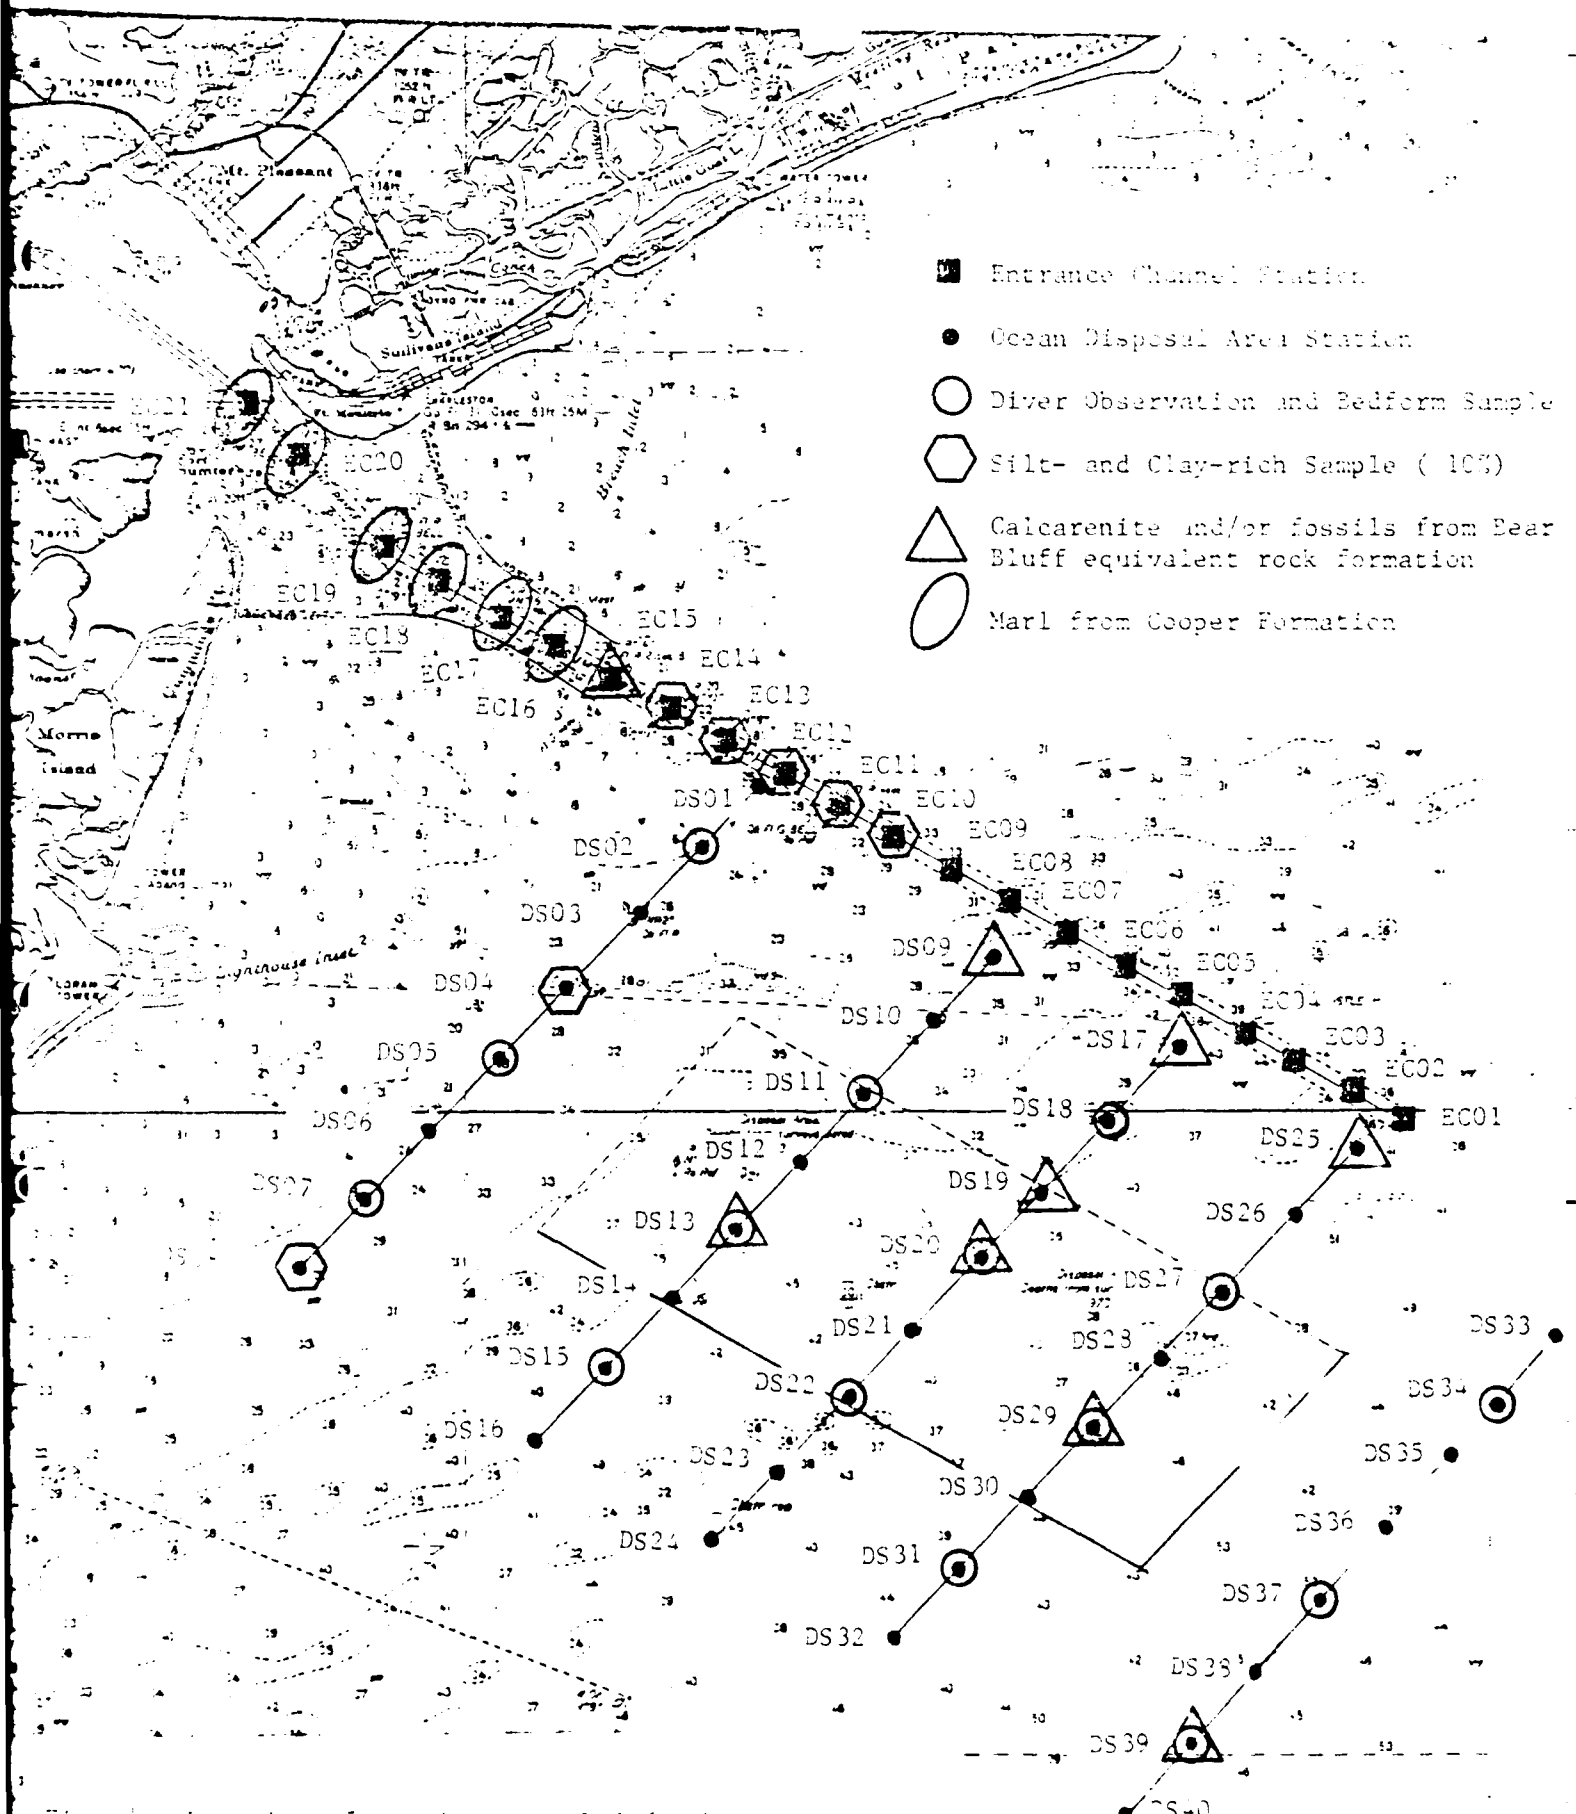


Fig. 4. Location of stations sampled for bottom sediments in the Charleston Entrance Channel and Charleston Harbor Disposal Area.

RESULTS AND DISCUSSION

Hydrography

The Charleston Harbor Ocean Disposal Area occurs in coastal marine waters beyond the harbor mouth, and salinities were all in the euhaline range (30-40°/oo) during field studies in August of 1978 (Table 1). Salinities were lowest along the innermost transect (averaging 33.38°/oo) and highest along the outermost transect (averaging 35.13°/oo). As expected, salinities at a given station were higher on bottom than at the surface, but differences seldom exceeded 3.0°/oo. Water temperatures were high and reflected the summer season when sampling was conducted. Temperature ranged from a low of 26.5°C in a bottom sample from station DS34 to a high of 30.1 C in a surface sample from station DS23. Most temperature readings were between 28 and 30 C, and differences from surface to bottom in most cases were rather small (Table 1). Oxygen concentrations were relatively high, given the warm temperatures and high salinity of the water. The lowest oxygen value observed was 4.0 mgl^{-1} in a surface sample from station DS02. Most values of oxygen ranged between 5.0-6.8 mgl^{-1} (Table 1). Values for other hydrographic parameters measured during the study, including turbidity, nutrients, and solids, are given in Table 1.

Epifaunal Assemblages

A total of 171 epifaunal (or partly epifaunal) macroinvertebrate species was distinguished in oyster dredge collections from the 40 stations in the study area during August, 1978 (Tables 2-42). In terms of species, the fauna was dominated by bryozoans (39 species), cnidarians (33 species), mollusks (28 species), and arthropods (27 species). These four groups accounted for 74.7% of the total number of species identified from the samples. Of the 171 species found, only

eight (the hydroid Clytia cylindrica, the bryozoans Membranipora tenuis, Microporella ciliata, and Parasmittina nitida, the sedentary polychaetes Sabellaria vulgaris and Hydroides dianthus, the bivalve Chama macerophylla, and the barnacle Balanus venustus) were found at 20 or more of the 40 stations. The most ubiquitous species was the barnacle Balanus venustus, which was present in samples from 29 stations. This species was common to abundant on suitable shelly substrates.

With a few exceptions, the study area was sparsely populated by epifaunal invertebrates. The bottom, consisting largely of sandy sediments with varying amounts of ground shell, provided an unsuitable substrate for most epibenthic species. The volume of most oyster dredge catches was very small, typically consisting of a few shells along with occasional decapods and echinoderms. Patches with large octocorals (Titanideum frauenfeldii), sponges, and other hard-bottom organisms were infrequent and quite localized, and none of the stations represented significant "live bottom" areas. Sand dollars (Mellita quinquiesperforata) were abundant in fine sand stations (DS01, DS02, DS03, and DS04) along the innermost transect, but elsewhere they were infrequent or absent.

Considerable variability was observed in the number of species from station to station in the study area (Fig.3). The number of species collected at a given site largely reflected the presence or absence of large shells, which provided substrate for the sessile epifauna. Species numbers were quite high where such substrates were present, and typically low where the bottom was sand or sand and ground shell only. A total of 40 or more species was identified in collections from nine of the stations (DS07, DS13, DS17, DS21, DS25, DS26, DS30, DS33, DS38). The maximum number of species (60) occurred in a sample from station DS25. The

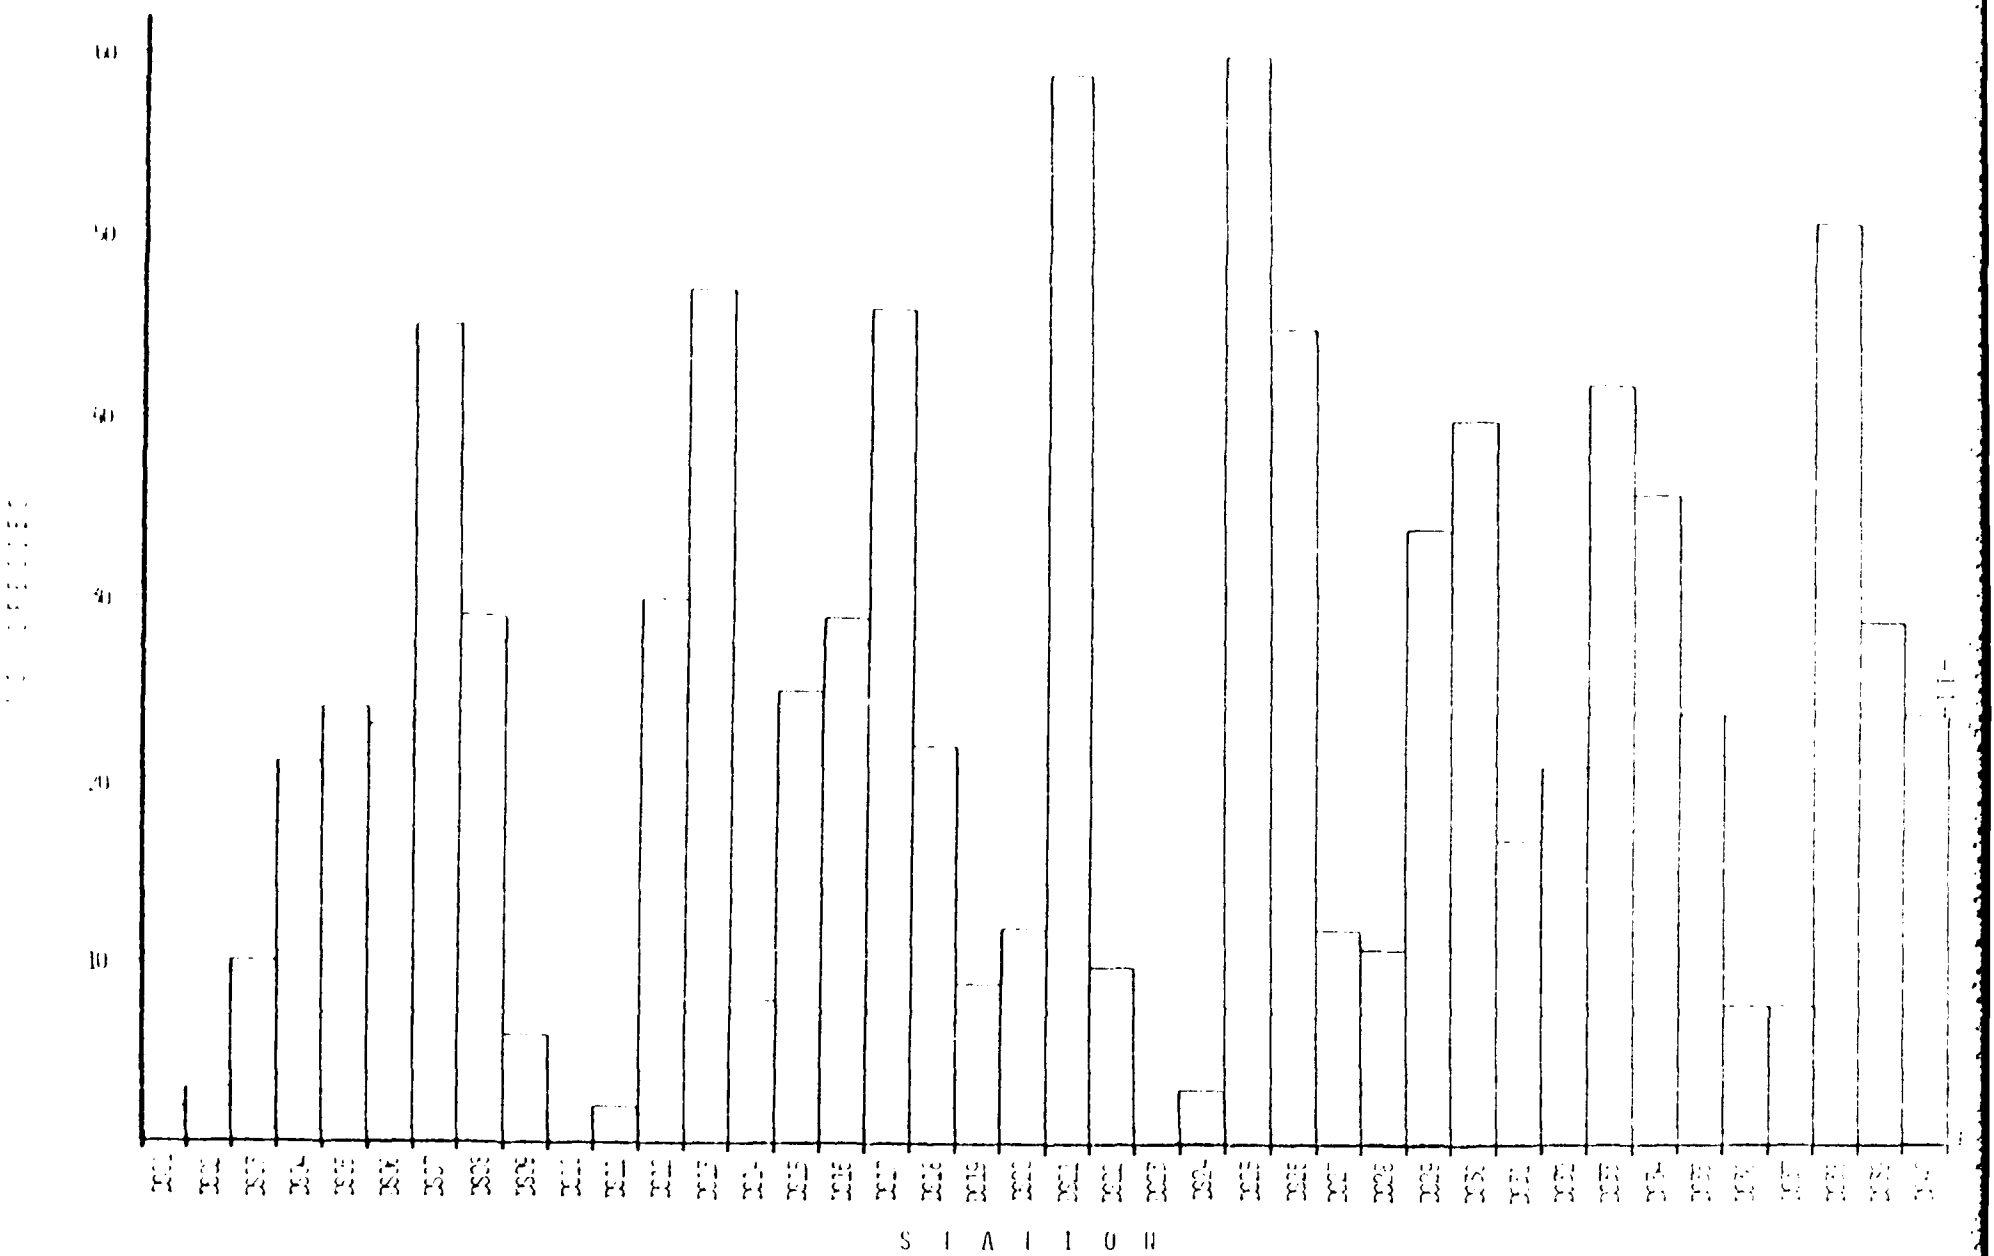

Fig. 3. Number of species in oyster dredge samples from 40 stations in the study area off Charleston, South Carolina.

were a number of species per station was 23.2.

No noteworthy differences was detected between the fauna of the Ocean Disposal Area and adjacent sites outside that could unequivocably be attributed to deposition of dredged material. Species numbers averaged 22.8 inside the Ocean Disposal Area and 23.3 outside. Faunal composition of the two areas was very similar, with 105 species identified inside the disposal area, 152 outside the site, and 80 species common to the two areas. The lower number of species from sites in the Ocean Disposal Area proper is believed to be due primarily to the smaller number of stations sampled there (only 12 of the 40 stations). In addition, the innermost and outermost transects, which did not cross the Ocean Disposal Area, were somewhat different in environmental characteristics and faunal composition from the three middle transects which did.

Infaunal Assemblages

A total of 33,952 benthic macroinvertebrates, representing 433 species, was obtained in quantitative Smith-McIntyre grab collections from the study area (Tables 43-82). Of the total number of organisms collected, 37.5% were polychaetes, 19.6% were the cephalochordate Branchiostoma caribaeum, 13.0% were amphipods, and 7.0% were pelecypods. Representatives of 24 other major taxa comprised the remaining 26% of individuals collected (Table 83). Polychaetes also dominated the fauna taxonomically, with 211 species accounting for 48.8% of the total. Pelecypods comprised 19.9% of the number of species, while decapods and gastropods contributed 9.9% each.

The most abundant single species in the samples was the lancelet, Branchiostoma caribaeum, which comprised nearly one-fifth of the total number of individuals. This species was collected at 31 of the 40 stations included in the study. B. caribaeum was either absent or present in low densities at

several of the shallower stations inshore, particularly those characterized by finer sediments (see Table 8). Maximum numbers were encountered at stations with bottoms of coarser sand; densities of 2750 and 2748 individuals m^{-2} were found at stations D033 and DS40, respectively. These concentrations exceed the maximum densities of 1343 lancelets m^{-2} recorded by Frankenberg and Leiper (1977) in summer samples from shelf waters off Georgia. In a study of the ecology and distribution of B. caribaeum on the shelf of the southeastern United States, Dory and Pierce (1967) found maximum densities of 204 individuals m^{-2} off Sapelo Island, Georgia. They noted that optimal conditions for aggregations of B. caribaeum included the presence of coarse, shelly, siliceous sand in areas of subsurface wave action and tidal current.

Ranking second in abundance was the sipunculid Aspidosiphon spinalis, which accounted for 3.4% of the total fauna. It was present in collections from 39 of the 40 stations sampled. Other species contributing more than 2% of the total fauna included the polychaetes Spiophanes bombyx, Goniadides carolinae, Spio pettiboneae, Nephtys picta, and Prionospio cristata, the lunulitiform bryozoan Cupuladria doma, the amphipod Trichophoxus floridanus, and nematodes of undetermined identity. The polychaete Spiophanes bombyx was the most ubiquitous species, occurring at all of the 40 stations sampled. Also widely distributed were the polychaete Nephtys picta (35 stations), Nemertina (undet.) A (37 stations), the amphipods Pseudoplatyischnopus floridanus and Tiron tropakis (33 stations each), nematodes (33 stations), the decapod Pagurus longicarpus (32 stations), and the pelecypods Tellina probiya and Tryllia concentrica (30 stations each).

Species diversity (H') ranged from 3.4 to 6.1 in samples from the study area (Table 4, Fig.). Diversity (H') did not reveal any significant

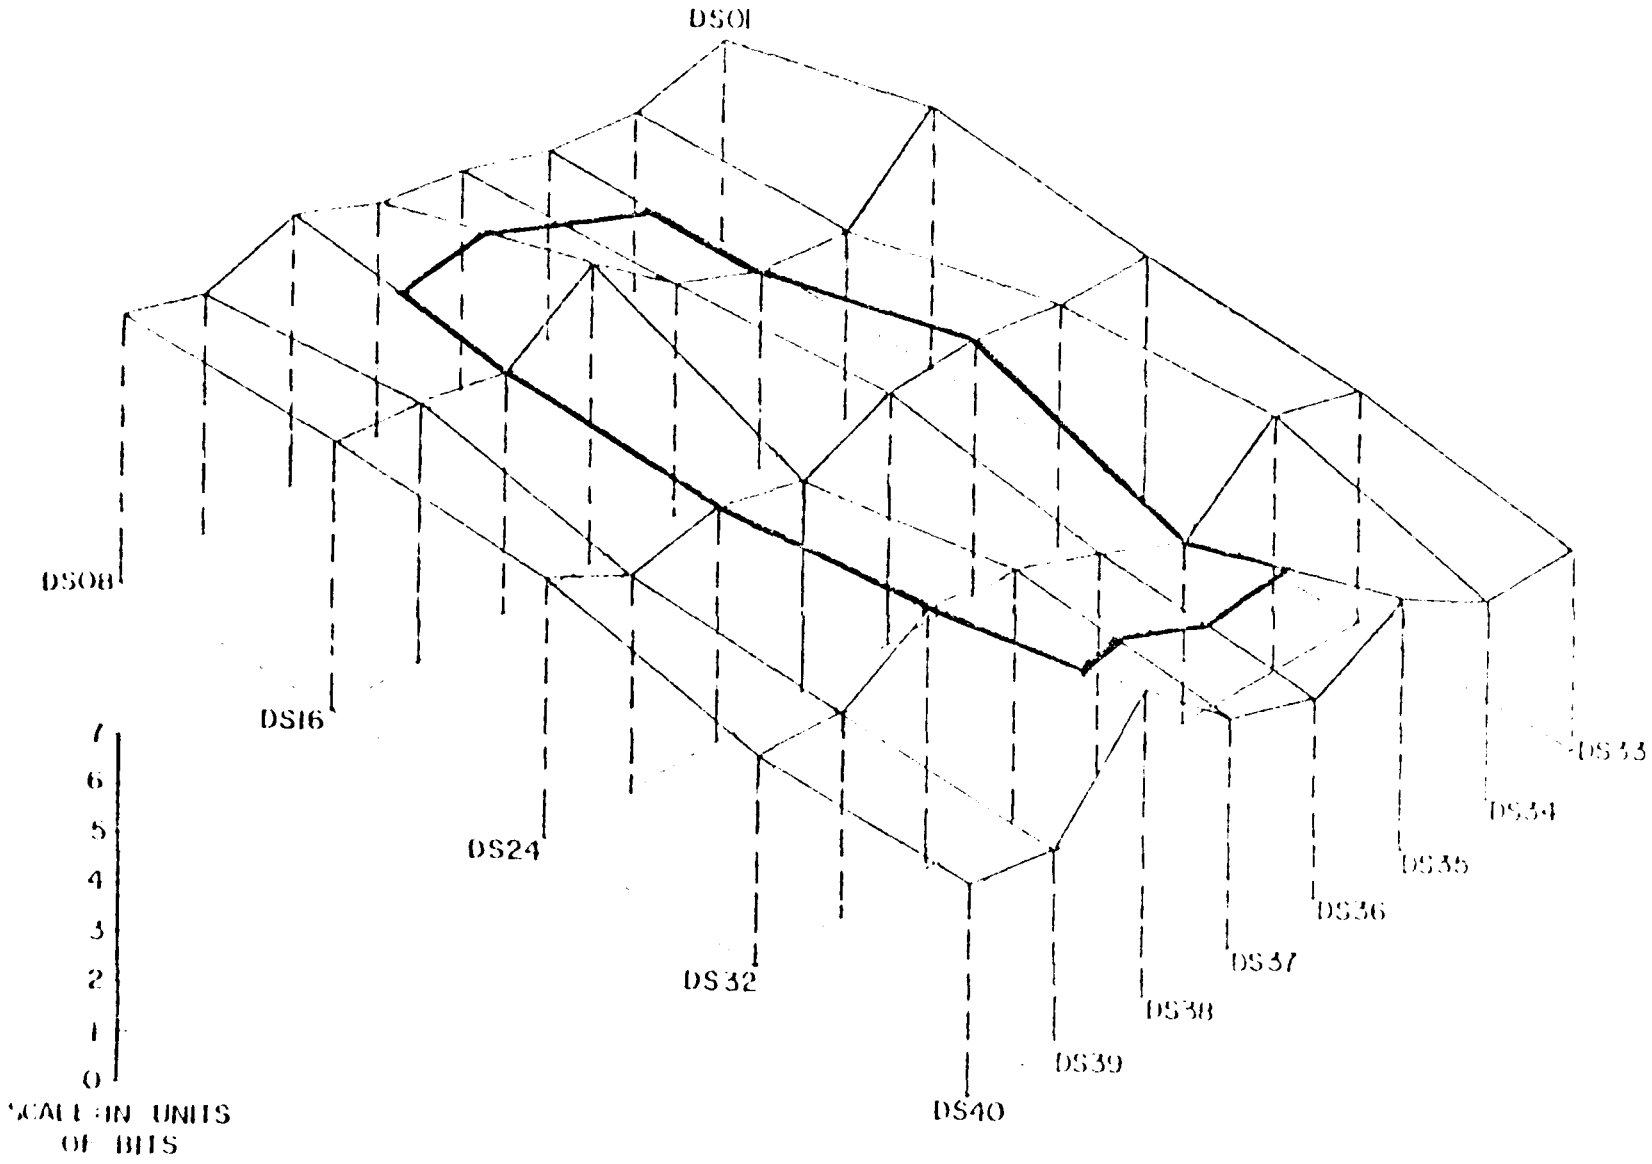

Figure 4. Species diversity values (H') for stations in and adjacent to the Charleston Harbor Ocean Disposal Area. Heavy solid lines indicate boundaries of disposal area.

[illegible] between stations inside and outside the disposal area. The mean value for H' was [illegible] for stations in the disposal area and [illegible] for the stations outside the area. Diversity values over the entire study area were generally higher than those observed in shallow shelf waters of Virginia (Boesch, 1972) and Rhode Island (Sanders, et al., 1962). The high observed H' is attributable in part to the species richness component of diversity, which ranged from 5.52 at DS10 to 22.00 at DS38 (Table B4). The number of species collected at these stations was 31 and 173, respectively. Neither the number of species per station nor species richness (SR) was significantly different between stations inside and outside the disposal area (ANOVA, $p > 0.5$). High diversities were also partly attributable to the evenness component (J'), which measures the distribution of individuals among species present. In spite of the numerical dominance of Branchiostoma caribaeum, 19 other species each contributed more than 1% of the total number of individuals collected. Yet these 20 species combined to account for only 56.4% of the total number of animals present. This is a substantially more even distribution of individuals within the species list than Dorjes (1972) found on transects off Georgia, where the 10 most abundant species contributed 86% of the total. Likewise, the 10 most abundant species of shallow nearshore infaunal communities at Murrells Inlet, South Carolina, contributed 80.2% of the total number of animals collected (Knott, Calder, and Van Dolah, unpublished data).

Many more species were identified from the study area off Charleston than were reported from similar areas off the Georgia coast in the recent publications. Collections from supratidal, intertidal, and subtidal shallow shelf areas out to depths of about 15 m off Sapelo Island yielded 295 species (Dorjes, 1972). Three stations sampled by Frankenberg and Leiper (1977) off Sapelo Island, with

sediment characteristics [illegible] the present study [illegible], yielded an average of [illegible] species [illegible] per station. By comparison, an average of 90 species per [illegible] were obtained from the study area of Wigley et al. (Table 5-1). As the only previous study of this nature in South Carolina, 123 species were identified in samples from nine intertidal and nine subtidal stations (maximum depths of 3 m) in the Murrells Inlet area (Knott, Calder, and Van Dolah, unpublished data). The infauna of sandy shelf areas on the southeastern continental shelf is therefore far from impoverished taxonomically. Likewise, faunal densities appear to be relatively high.

Sediment Geochemistry

Data resulting from the chemical analysis of sediment samples collected in and adjacent to the Charleston Harbor Ocean Disposal Area are presented in Table 5-5. These analyses did not reveal any substance exceeding maximum recommended for the determination of the acceptability of dredged material disposal to the nation's waters. Suspended sediment-time curves for the samples are given in Figs. 5-28.

Sedimentologic Investigations

A) Charleston Harbor Entrance Channel:

Analyses of bottom grab samples taken every 0.5 nautical mile from a point opposite Ft. Moultrie to the seaward beginning of the maintained channel have defined 3 distinct composition zones:

1) scoured bedrock (calcarenite and marl) covered with a thin veneer of calcium carbonate shell-rich quartz sand stretches between Ft. Moultrie and the seaward end of the jetties (stations EC21 to EC13, Fig. 2 and Table 5-6).

Figure 26. Suspended sediment-time curves for samples from station D5C0.

(2) sandy, clayey silt poor in calcium carbonate shell material extends from the seaward end of the jetties to approximately 3.5 nautical miles seaward of buoy "4" (stations EC14 to EC10, Fig. 2 and Table 8a).

(3) calcium carbonate shell-rich quartz sand extends seaward to the beginning of the maintained channel (stations EC9 to EC01, Fig. 2 and Table 8b).

The 46 individuals phi-normal quartz components extracted from the 21 station samples were classified into 6 unique textural groups. These phi-normal components were extracted from cumulative frequency data by the computer program ROSE (Clark, 1976). This classification is based on mean grain size and sorting or standard deviation and was accomplished through cluster analysis, inspection, and step-wise discriminant analysis. These individual phi-normal quartz components are each considered to represent a depositional response to various interacting parameters, i.e., wave-tidal currents and available sediment supply, effecting sedimentation at the sampled stations. The following three major groups containing 72% of the phi-normal quartz components were identified:

Group 1: 10 members, mean grain size of 2.41 ± .13 phi, sorting of 0.30 ± .14 phi units.

Group 2: 14 members, mean grain size of 2.78 ± .19 phi, sorting of 0.10 ± .06 phi units.

Group 3: 9 members, mean grain size of 3.09 ± .37 phi, sorting of 0.34 ± .19 phi units.

The membership of these groups is presented in Table 37.

Using a goodness of fit statistical test, the hypothesis of equal distribution over the three previously mentioned zones was rejected at the 99% confidence level only for Group 3 (see Table 38). Group 3 appears to be localized in Zone 2, the "channel", which is clay- and silt-rich. Inspection of the membership of groups characterized by coarser mean grain sizes

and [illegible] (Table 89) indicate that they [illegible] also not [illegible] within [illegible].

The sampled [illegible] stations are from that portion of the [illegible] channel cut into the 24 foot- to 30 foot-deep nearshore shelf seaward of the jetties. This man-made "canyon" is providing a basin suitable for silt and clay deposition. Furthermore, silt and clay deposition within this "canyon" is much more important than sand deposition, at least in the [illegible] grab samples (Table 89). The existence of this very fine sandy, clayey silt deposit raises questions concerning 1) sand transport both on the shoals flanking Charleston Harbor Entrance and in the nearshore region and 2) the depositional fate of silts and clays (potentially pollutant bearing) leaving Charleston Harbor.

B) Charleston Harbor Offshore Disposal Area:

The only direct sedimentologic evidence of Entrance Channel spoil disposal in this region was the presence of fresh calcarenite rock and fossil fragments from geologic formations exposed on the bottom between the jetties. These were found at 4 stations within and 4 stations without the Offshore Disposal Area (Fig. 2). The calcarenite rock fragments are from Bear Bluff equivalent beds (Upper Pliocene in age) as are the fossils, large scallops (Chlamys aborea). No recognizable Cooper Formation rock fragments (marl) were observed. This calcarenite rock was sampled at Entrance Channel station EC15 (Fig. 2).

The bottom sediments of the Offshore Disposal Area are calcium carbonate shell-rich quartz sands (Tables 89 and 90) exhibiting symmetric, wave-generated ripple marks (Table 91). Of the 15 stations observed by divers 13 had symmetric, wave-generated ripple marks with crests oriented NW-SE, 1 had asymmetric ripple marks indicating northward transport, and 1 had a flat bed (Table 91). These symmetrical ripple marks, although sand was not observed to be moving, were

probably a bedform response to recent swell and sea. Bottom sediments in the Offshore Disposal Area are not below wave base and are thus transported under local swell and sea conditions.

These bottom sediments typically contain two phi-normal quartz components, one coarser in grain-size and poorer in sorting than the other (Tables 89 and 90). Ripple mark crests and troughs could be differentiated texturally and compositionally only at stations DS34 and DS39 (Tables 90 and 91). At all the other stations crests and troughs are texturally and compositionally identical.

The 253 individual phi-normal quartz components extracted from bottom sediment samples collected at 40 stations were classified into 16 unique textural groups. These phi-normal components were extracted from cumulative frequency data using the computer program BOKE (Clark, 1976). This classification is based on mean grain size and sorting or standard deviation and was accomplished through cluster analysis, inspection, and step-wise discriminant analysis. The individual phi-normal quartz components are each considered to represent a depositional response to various interacting parameters, i.e., wave-tidal currents and available sediment supply, effecting sedimentation. The following six major groups [illegible] of the phi-normal quartz components were identified:

Group 1: 23 members, mean grain size of 1.01 ± .13 phi, Sorting of 0.55 ± .04 phi units.

Group 5: 41 members, mean grain size of 2.00 ± .08 phi, Sorting of 0.56 ± .09 phi units.

Group 6: 29 members, mean grain size of 2.35 ± .11 phi, Sorting of 0.51 ± .07 phi units.

Group 8: 42 members, mean grain size of 2.31 ± .06 phi, Sorting of 0.[illegible] ± .[illegible] phi units.

Group 9: 26 members, mean grain size of 2.50 ± .06 phi, Sorting of 0.34 ± .04 phi units.

Group 10: 26 members, mean grain size of 2.67 ± .05 phi, Sorting of 0.26 ± .05 phi units.

The membership of these groups is presented in Table 92.

Using a goodness-of-fit statistical test, the hypothesis of equal distribution within and without the disposal area was rejected at the 90% confidence level only for Group 10 (Table 93). Group 10 alone appears to be preferentially located within the Charleston Harbor Offshore Disposal Area. The hypothesis of equal distribution over the five shore-parallel transects was rejected at the 90% confidence level for Groups 1, 5, 6, 9, and 10 (Table 94). Group 8 alone failed to be rejected. The hypothesis of equal distribution over 4 shore-perpendicular transects was rejected at the 90% confidence level for Groups 1, 8, 9, and 10 (Table 95). Groups 5 and 6 failed to be rejected. These tests were made to analyze the geographic distribution of these groups over the study region.

Rejection of both the shore-parallel and shore-perpendicular hypotheses suggests a distribution of isolated points. This is indicated for Groups 1, 9, and 10. In addition, Group 10 is restricted to the Disposal Area proper.

Rejection of only the shore-parallel hypothesis suggests a distribution of shore-parallel bands and is indicated for Groups 5 and 6. Inspection of the actual distribution of Group 5 members over the 5 shore-parallel transects shows that they are concentrated in two non-adjacent bands (Table 94). This situation may not be the result of shoreward sand transport but could reflect local, shore-parallel sources. However, inspection of the distribution of Group 6 members over the 5 shore parallel transects shows a steady concentration

of members toward the nearshore and away from the offshore (Table 94). This may be indicative of shoreward transport of finer grained sands winnowed from sediments lying further offshore.

Rejection of only the shore-perpendicular hypothesis suggests a distribution of shore-perpendicular bands and is indicated for Group 8. However, inspection of the actual distribution of Group 8 members over the 4 shore-perpendicular transects (Table 94) shows that they are almost equally concentrated in two non-adjacent bands. This situation may not be the result of sand transport NE-SW across the near-shore shelf, but could result from shoreward transport from isolated point sources.

In summary, the only direct evidence of Entrance Channel spoil found in the study area was the presence of fresh calcarenite pebbles and fossils from geologic formations exposed on the bottom between the jetties. The sandy bottom throughout the study area is ripple marked, an indication that swell and sea move sediment over the entire region - no portion of the study area can be considered below "wave base." Analysis of phi-normal plots indicates a minimum of 6 unique major textural or grain size groups present in the study area, only one of which is restricted to the Disposal Area proper. Isolated point sources characterize the geographic distributions of three of these groups and are indirectly indicated for 2 more. The remaining group is distributed in shore-parallel bands with members being concentrated in the nearshore bands and deficient in the offshore.

CONCLUSIONS

The Charleston Harbor Ocean Disposal Area is located on the inner continental shelf midway along the coast of South Carolina. Water depths in the area vary from about 10-16 m, and bottom sediments are sandy. Investigations were conducted in and adjacent to the Ocean Disposal Area during the summer and autumn of 1978 to assess the benthic communities and sediment characteristics of the area in relation to disposal of dredged materials over the site.

Waters of high salinity and moderate dissolved oxygen content cover the study area. During August field sampling, salinities varied from 31.32-35.83°/oo, while oxygen concentrations ranged from 4.0-6.9 mg/l. Turbidities decreased progressively with increasing distance from shore, so that water clarity was markedly greater offshore.

Shifting sands provide an unsuitable substrate for most sessile species, and the study area was sparsely populated with epifaunal invertebrates except in areas where accumulations of large shells were present. The number of species in dredge collections varied widely from one station to another. These differences were related to the presence or absence of suitable substrate rather than any effects from disposal of dredged materials in the area. The amount of material collected by the dredge was small at each of the 40 stations sampled. Although sponges, octocorals, hydroids, bryozoans, and ascidians were occasionally taken in the dredge, no live bottom areas were found anywhere in the study area. No noteworthy differences in epifaunal composition were detected between the Ocean Disposal Area and adjacent sites outside that could be directly attributed to disposal practices.

Although the bottom of the study area appears to constitute a relatively uniform habitat, an unexpectedly large variety of infaunal invertebrates were found in grab samples. Thorough taxonomic workup of these collections resulted in the identification of 493 species. This study shows that benthic communities of the inner continental shelf in this region are faunistically richer and have higher species diversity than previously thought. Most of the constituent species are small, and polychaete worms dominated the fauna both in numbers of species (211) and overall abundance (37.5% of the fauna). The most abundant species was the lancelet Branchiostoma caribaeum, a seasonally abundant organism which accounted for nearly 20% of the total number of animals collected. Lancelets were found in much greater concentrations than have been recorded before from the southeastern continental shelf, reaching maximum densities of 2788 individuals m^{-2}. The detailed account of benthic community structure provided by this report provides a data base for appraising the effects of future dredged material disposal in the area.

Variation in species numbers, faunal density, species diversity, and species richness were noted from one station to another. However, differences between sites inside and outside the Ocean Disposal Area were not statistically significant. No effects of dredged material disposal were detectable on either epifaunal or infaunal communities. Such practices have probably had little lasting impact on the macrobenthos because of the similarity of dredged materials to the existing sediments of the disposal area. On the other hand, the impact of dredged materials of a different particle size, such as silts from Charleston Harbor, would probably be significant if these sediments were not rapidly diluted and dispersed from the area by water currents. If such material settled out to form a mound at the disposal area, the impact would be [illegible] as long as it remained unburied by the site.

The only direct evidence of Entrance Channel shell found in the study area was the presence of fresh calcarenite pebbles and fossils from geologic formations exposed on the bottom between the jetties. The sand bottom throughout the study area is ripple marked, an indication that swell and sea move sediment over the entire region - no portion of the study area can be considered to be below "wave base." There are a minimum of 6 unique textural or grain size groups present in the study area, only one of which is restricted to the Disposal Area proper. Isolated point sources characterize the geographic distributions of 3 of these groups and are indirectly indicated for 2 more. One group is distributed in shore-parallel bands with members being concentrated in the nearshore bands and deficient in the offshore.

Table 2. List of epifaunal species collected in oyster dredge samples, and their frequency of occurrence at 40 stations in the study area.

Species	Occurrence at Number of Stations
Phylum Porifera	
Cliona sp.	13
Leucosolenia canariensis	5
Porifera (undet.)	3
Spheciospongia vesparia	1
Orange sponge (undet.)	1
Phylum Cnidaria	
Clytia cylindrica	25
Astrangia danae	17
Turritopsis nutricula	16
Schizotricha tenella	15
Eudendrium sp.	14
Dynamena cornicina	13
Telesto sanguinea	12
Ectopleura dumortieri	11
Halecium dysymmetrum	8
Telesto fruticulosa	8
Leptogorgia setacea	7
Zanclea costata	5
Actiniaria (undet.)	4
Halecium sp.	3
Lovenella grandis	3
Titanideum frauenfeldii	3
Chrysaora quinquecirrha (polyp)	2
Leptogorgia virgulata	2
Lovenella gracilis	2
Monostaechas quadridens	2
Plumularia floridana	2
Proboscidactyla ornata	2
Bougainvillia sp.	1
Campanulina sp.	1
Clytia fragilis	1
Clytia kincaidi	1
Clytia paulensis	1
Cuspidella humilis	1
Epizoanthus americanus	1
Hydractinia echinata	1
Lophogorgia hebes	1
Pandeidae (undet.)	1
Sertularella conica	1
Phylum Platyhelminthes	
Tubellaria (undet.)	5
Phylum Rhynchocoela	
Nemertean (undet.)	1
Phylum Entoprocta	

Table 2. (continued)

Species	Occurrence at Number of Stations
Barentsia sp.	1
Entoproct (undet.)	1
Phylum Bryozoa	
Parasmittina nitida	24
Membranipora tenuis	23
Microporella ciliata	21
Schizoporella cornuta	17
Aetea anguina	15
Cribrilaria radiata	14
Hippopleurifera mucronata	13
Hippoporina verrilli	12
Phylactella aviculifera	12
Trypsostega venusta	9
Cleidochasma porcellanum	8
Cyclostomata A (undet.)	8
Schizoporella errata	8
Bowerbankia gracilis	7
Crisia sp.	7
Floridina parvicella	7
Hippoporella uvulifera	7
Copidozoum tenuirostre	6
Lichenopora sp.	6
Celleporidae (undet.)	4
Reptadeonella violacea	3
Sundanella sibogae	3
Aeverrillia setigera	2
Amathia distans	2
Caulibugula pearsei	2
Cribrilina floridana	2
Cryptosula pallasiana	2
Hippaliosina rostrigera	2
Hippoporina contracta	2
Alcyonidium hauffi	1
Amathia alternata	1
Amathia sp.	1
Anasca A (undet.)	1
Celleporina hassalli	1
Ctenostomata (undet.)	1
Discoporella umbellata	1
Electra monostachys	1
Membranipora arborescens	1
Nolella stipata	1
Phylum Sipuncula	
Sipunculid (undet.)	14
Phylum Echiura	
Echiurid (undet.)	1
Phylum Annelida	
Hydroides dianthus	27
Sabellaria vulgaris	22
Lepidonotus sublevis	13

Table 2. (continued)

Species	Ocurrence at Number of Stations
Hypsicomus phaeotaenia	11
Pomatoceros caeruleus	10
Polychaeta A (undet.)	2
Polydora sp.	1
Sabellidae (undet.)	1
Phylum Mollusca	
Chama macerophylla	21
Crepidula fornicata	14
Anadara transversa	13
Ostrea equestris	13
Anomia simplex	10
Chaetopleura apiculata	8
Crepidula plana	8
Mitrella lunata	8
Octopus vulgaris	4
Anachis translirata	3
Musculus lateralis	3
Oliva sayana	3
Polinices duplicatus	3
Eupleura caudata	2
Modiolus modiolus squamosus	2
Acanthodoris pilosa	1
Argopecten gibbus	1
Dinocardium robustum	1
Didora cayenensis	1
Diplothyra smithi	1
Fasciolaria lilium hunteria	1
Gastropoda (undet.)	1
Lithophaga bisulcata	1
Muricidae (undet.)	1
Prunum apicinum	1
Sinum perspectivum	1
Turbo castanea	1
Urosalpinx cinerea	1
Phylum Arthropoda	
Balanus venustus	29
Balanus calidus	12
Ovalipes stephensoni	11
Kochlorine floridana	8
Xanthidae (undet.)	7
Pilumnus sp.	5
Portunus gibbesii	5
Caprellidae (undet.)	3
Pagurus pollicaris	3
Podochela sidneyi	3
Libinia dubia	2
Ovalipes ocellatus	2
Portunus spinimanus	2
Squilla empusa	2
Balanus galeatus	1

Table 2. (continued)

Species	Ocurrence at Number of Stations
Balanus improvisus	1
Callinectes sapidus	1
Chelonibia patula	1
Hepatus pudibundus	1
Hypoconcha sabulosa	1
Metoporhaphis calcarata	1
Micropanope xanthiformis	1
Paguridae (undet.)	1
Pilumnus sayi	1
Synalpheus townsendi	1
Tanystylum orbiculare	1
Trachypenaeus constrictus	1

Table 88. Goodness-of-fit tests for the three (3) major unique textural groups identified from the quartz phi-normal components of Charleston Entrance channel bottom sediments. The null hypothesis being tested is that of equal distribution over the 3 zones.

GROUP 1: χ^2 = 2.84, 2 D.F.

	EXPECTED	OBSERVED
Zone 1 (Jetties)	3.04	4
Zone 2 ("Canyon")	2.17	0
Zone 3 (Shelf)	4.78	6

GROUP 4: χ^2 = 1.71, 2 D.F.

	EXPECTED	OBSERVED
Zone 1 (Jetties)	4.26	3
Zone 2 ("Canyon")	3.04	5
Zone 3 (Shelf)	6.70	6

GROUP 5: χ^2 = 6.21*, 2 D.F.

	EXPECTED	OBSERVED
Zone 1 (Jetties)	2.74	1
Zone 2 ("Canyon")	1.96	5
Zone 3 (Shelf)	4.30	3

*Reject the null hypothesis of equal distribution at the 90% confidence level.

Table 93. Goodness-of-fit tests for the six (6) major unique textural groups identified from the quartz phi-normal components of Charleston Harbor Offshore Disposal Study Area bottom sediments. The null hypothesis being tested is that of equal distribution Inside of and Outside of the Charleston Harbor Offshore Disposal Area proper.

GROUP 1: $\chi^2 = .10$, 1 D.F.

	EXPECTED	OBSERVED
Inside	8.74	8
Outside	14.26	15

GROUP 5: $\chi^2 = .03$, 1 D.F.

	EXPECTED	OBSERVED
Inside	15.58	15
Outside	25.42	26

GROUP 6: $\chi^2 = 2.45$, 1 D.F.

	EXPECTED	OBSERVED
Inside	7.6	11
Outside	12.4	9

GROUP 8: $\chi^2 = .09$, 1 D.F.

	EXPECTED	OBSERVED
Inside	15.96	15
Outside	26.04	27

Table 93. (Continued)

GROUP 9: χ^2 = .08, 1 D.F.

	EXPECTED	OBSERVED
Inside	9.88	10
Outside	16.12	16

GROUP 10: χ^2 = 20.19*, 1 D.F.

	EXPECTED	OBSERVED
Inside	9.88	21
Outside	16.12	5

*Reject null hypothesis of equal distribution at the 90% confidence level.

Table 94. Goodness-of-fit tests for the six (6) major unique textural groups identified from the quartz phi-normal components of Charleston Harbor Offshore Disposal Study Area bottom sediments. The null hypothesis being tested is that of equal distribution over shore-parallel transects.

Group 1: x^2 = 11.86*, 4 D.F.

Stations	Expected	Observed
1-8	4.14	1
9-16	4.83	0
17-24	4.71	8
25-32	4.71	7
33-40	4.60	7
